SECURITY ASSESSMENT REPORT

TryHackMe – Learning Cyber Security

REPORT ID	AZ-EH-2026-002
VERSION	1.0
ASSESSMENT DATE	17/10/2026
REPORT DATE	22/10/2026
PREPARED BY	Ammar Alzaiem
CLASSIFICATION	Public

Overview

This room gives a short introduction to some of the main areas of cybersecurity. It covers why understanding web applications and networks matters, and provides a roadmap for continuing to learn.

The main idea is that hacking isn't just about using tools. You need to understand how a system works before you can identify weaknesses in it.

1. Web Application Security

Web applications are common targets because they handle user accounts, data, and interactions between users and servers.

To find vulnerabilities, you first need to understand how the application works. For example, a login page accepts user input and uses it to decide whether someone can access an account. If that process has a weakness, an attacker might be able to bypass authentication or access another user's account.

A vulnerability is a weakness in a system that could be exploited to affect its security.

This section introduced the idea through BookFace, a deliberately vulnerable social media application provided by TryHackMe.

2. Network Security

Networking is another important foundation in cybersecurity. Computers communicate over networks, and understanding that communication helps when investigating attacks or securing systems.

For penetration testing, networking knowledge is useful for identifying hosts, discovering open ports, and understanding which services are running. For defensive security, it helps with analysing network traffic, reviewing logs, and investigating suspicious activity.

The room uses the Target data breach as an example of the consequences of a security incident.

3. Learning Roadmap

Cybersecurity covers several different areas, so having a learning path helps organise what to study next.

The room introduces a progression from learning the fundamentals to exploring more specialised areas, such as offensive security and cyber defence.

Offensive security focuses on finding and validating weaknesses in systems, while defensive security focuses on detecting attacks, investigating incidents, and protecting systems.

Since I am interested in penetration testing, I want to build a solid foundation in networking, Linux, and web technologies before moving further into exploitation and more advanced labs.

Conclusion

This room was a starting point for understanding what cybersecurity involves and why the fundamentals matter. Web applications and networks are two areas I will keep studying because they are directly relevant to penetration testing.

The main lesson is simple: before trying to break something, understand how it works.
